

a

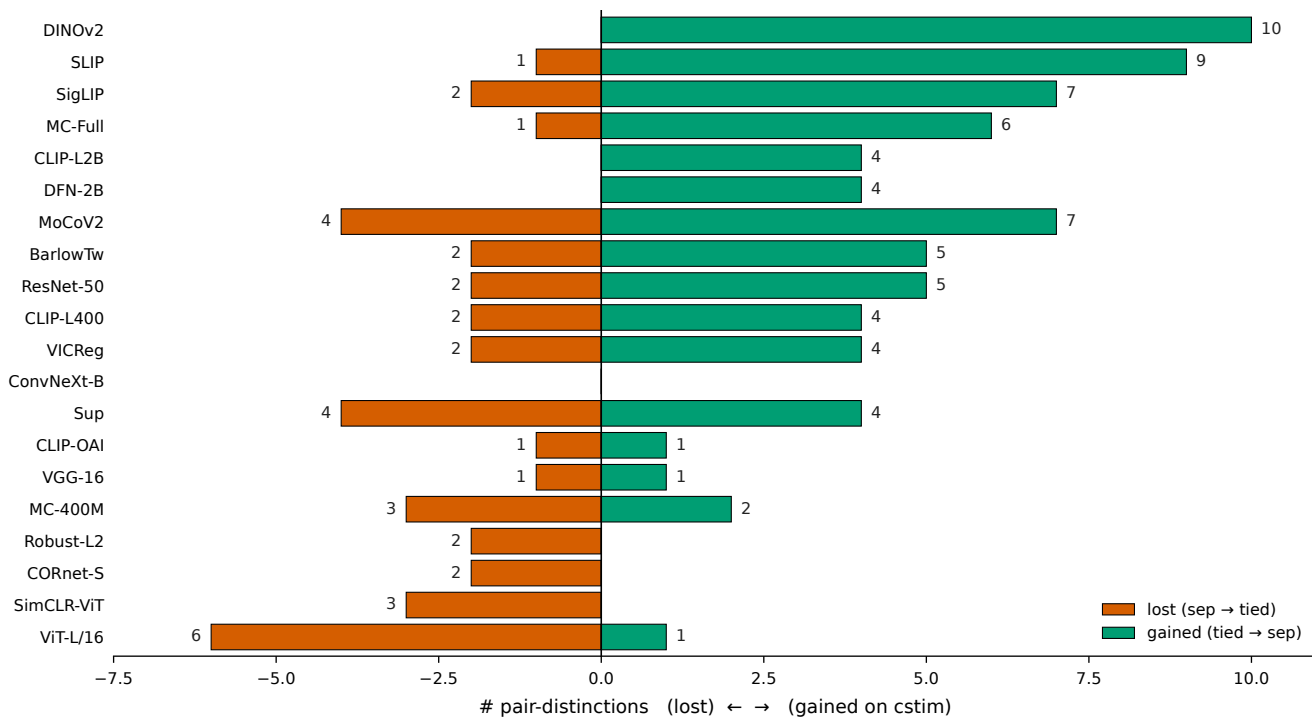

Of 190 model pairs, 57 are statistically indistinguishable on baseline natural images. On cstim images, 37 (65%) become distinguishable.

We test each of $\binom{20}{2}=190$ pairs of models for whether subject-level RSA scores differ (paired t, FDR $q<0.05$) and label each pair by its outcome:

b

Each model's contribution to discriminability gain (cstim vs baseline)

c

Conversion rate by architecture-family relationship
